Does a photovoltaic panel reduce runoff and sediment in a slope?

The impact of a photovoltaic (PV) panel on runoff and sediment in a slope was tested. The key impact of the PV panel is preventing soil detachment by raindrop impacts. The PV panel slope produced 27 %-63 % less soil erosion than the control slope. The PV panel delayed runoff start time under rainfall with heavy rainfall intensities.

Why does a PV panel run off faster on a control slope?

Because the PV panel quickly concentrated rain water at downslope area, the runoff started faster on the PV panel slope; while the runoff generated slowly on the control slope due to the moderate rainfall intensity.

What is the difference between a control slope and a PV panel?

On the contrary, under heavy rainfall with 80 mm hr<sup>-1</sup> or 100 mm hr<sup>-1</sup> intensity, the runoff start time of the PV panel slope was later than the control slope. The rain water quickly filled the depressions and converged into overland flow on the control slope.

Why did a PV panel erode a slope section?

This was attributed to the weakened splash erosion on the slope section under the PV panel due to the rainfall interception by the panel, which indicated that the key impact of the PV panel was preventing soil detachment by raindrop impacts.
